Concentration Measures for the Beef Packing Industry

Azzam and Anderson reviewed the literature on structure, conduct, and performance issues related to the meatpacking industry (USDA, GIPSA,1996). They reviewed studies under two classifications: Structure, Conduct, and Performance (SCP) and New Empirical Industrial Organization (NEIO). Results were not consistent across studies for either classification.

SCP Studies

Azzam and Anderson reported that several studies of beef and pork packing concluded that market power, the ability to affect prices because of quantities transacted or market share affected by one or a few firms, can arise from concentration. However, the studies they reviewed, which differed widely in time period and analytical method, arrived at conflicting results. Some studies were faulted in that their observed correlations could be due to shifts in supply or demand not properly specified. Specifically, Azzam and Anderson alleged that links between supply elasticity and prices were not addressed in the regional price-concentration studies they reviewed. They also pointed out that economies of size rather than noncompetitive behavior, may be the cause of firm growth and increases in concentration.

NEIO Studies

Azzam and Anderson likewise reported a lack of consistent results across NEIO studies they reviewed. A pattern of results suggested exercise of market power in live cattle markets, but price effects seemed small and perhaps more than offset by cost reductions associated with consolidation. Market power did not increase with concentration as theory would suggest, and evidence indicated that packers were unable to sustain cooperation in restraining prices paid for cattle. They also concluded that empirical implementation has not equaled theoretical rigor due to lack of appropriate data and model complexity.

GIPSA Conclusions

GIPSA reported its conclusions from the Azzam and Anderson study as follows:

The researchers' description of historical industry evolution suggests that changes in the meatpacking industry have resulted from technological change and dynamic rivalry between firms. The basic question addressed by this project was whether the evidence from Structure-Conduct-Performance and New Empirical Industrial Organization studies is persuasive enough to warrant the conclusion that competition in the meatpacking industry is deficient. Taken as a whole, the literature review led to the conclusion that the answer is no.

Many SCP studies indicated the existence and exercise of market power. However, the failure to use appropriate theoretical models of conduct in these studies makes industry generalizations questionable.

The NEIO studies show a persistent gap between the actual price of livestock and the competitively determined price predicted by theory. However, the studies have not incorporated sufficient detail to prove noncompetitive behavior.

Empirical Measures of Packer Concentration

As discussed above, the CR-4 (four-firm concentration ratio) for steer and heifer slaughter as reported by GIPSA rose to 50 percent in 1985, 72 percent in 1990, and 80 percent in 1996 (preliminary GIPSA, table 3). The CR-4 for boxed fed beef production for the same years was 62 percent, 79 percent, and 84 percent (1994). Tables 3 to 6 summarize these and additional comparisons.

The Herfindahl-Hirshman Index

Another, generally preferred, measure of concentration is the Herfindahl-Hirshman Index (HHI), also reported by GIPSA. The HHI has the advantage of taking into account the number of firms and relative distributional shares of the market held by all firms, not just the largest few. The HHI is calculated by summing each firm's squared percentage of the market. If 100 firms each have a 1-percent share, the HHI will equal 100. If 1 firm has 100 percent of the market, the HHI equals 10,000.

¹Slaughter plants came under Federal inspection in the following 20 States after 1972: AR-6/81; CA-4/76; CO-7/75; CT-10/75; ID-7/81; KY-1/72; ME-5/80; MA-1/76; MD-3/91; MI-10/81; MO-8/82; NV-7/73; NH-8/78; NJ-7/75; NY-7/75; OR-7/72; PA-7/72; RI-10/81; TN-10/75 and WA-6/73. Many non-federally inspected plants can only custom slaughter for others.

Source: U.S. Dept. of Agriculture, Packers and Stockyards Statistical Report: 1995 Reporting Year, GIPSA 97-1, September 1997, Table 18.

²Plants reporting to GIPSA include federally and non-federally inspected establishments. Firms purchasing less than 2,000 head of all livestock, or less than 1,000 head of cattle prior to 1977, or less than \$500,000 of all livestock beginning in 1977 were not required to report to GIPSA.

The U.S. Department of Justice and Federal Trade Commission Horizontal Merger Guidelines (April 1992) provide insight into the HHI levels considered important in determining whether mergers within a relevant market are likely to be challenged by the Justice Department:

Post-Merger HHI below 1,000. The Agency regards markets in this region to be unconcentrated. Mergers resulting in unconcentrated markets are unlikely to have adverse competitive effects and ordinarily require no further analysis.

Post-Merger HHI between 1,000 and 1,800. The Agency regards markets in this region to be moderately concentrated. Mergers producing an increase in the HHI of less than 100 points in moderately concentrated markets post-merger are unlikely to have adverse competitive consequences and ordinarily require no further analysis. Mergers producing an increase in the HHI of more than 100 points in moderately concentrated markets post-merger potentially raise significant competitive concerns depending on the factors set forth in Sections 2-5 of the Guidelines.

Post-Merger HHI above 1,800. The Agency regards markets in this region to be highly concentrated. Mergers producing an increase in the HHI of less than 50 points, even in highly concentrated markets post-merger, are unlikely to have adverse competitive consequences and ordinarily require no further analysis. Mergers producing an increase in the HHI of more than 50 points in highly concentrated markets post-merger potentially raise significant competitive concerns, depending on the factors set forth in Sections 2-5 of the Guidelines. Where the post-merger HHI exceeds 1,800, it will be presumed that mergers producing an increase in the HHI of more than 100 points are likely to create or enhance market power or facilitate its exercise. The presumption may be overcome by a showing that factors set forth in Sections 2-5 of the Guidelines make it unlikely that the merger will create or enhance market power or facilitate its exercise, in light of market concentration and market shares (Section 1.5).

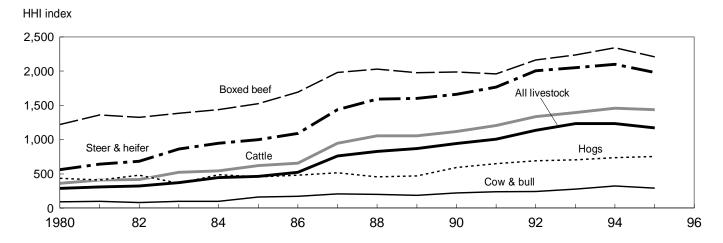

The HHI for U.S. steer and heifer slaughter was 999 in 1985, 1,661 in 1990, and 1,982 in 1995, above the threshold 1,800 level (fig.15). For all cattle slaughter combined, the HHI's are much lower, reaching only 1,437 in 1995. For U.S. boxed fed beef, the HHI's are 1,527; 1,988; and 2,208, respectively. If the relevant market were defined as steer and heifer slaughter or boxed fed beef production by the U.S. Department of Justice, it would seem that future major mergers would be candidates for challenge. On the other hand, if the relevant market were defined as cattle slaughter or all livestock purchases, merger challenges would be less likely (tables 3 to 6).

HHI and Our Asymmetric Model

It is clear that steer and heifer slaughter concentration and fed boxed beef concentration is high by several standards. It is far less clear what caused industry consolidation or what effects stem from high concentration, and whether any effects constitute market distortions adverse to producers.

We tested for the effects of concentration by including the HHI in our asymmetric model. We had HHI measures for only a limited part of the sample. The HHI was statistically significant in the sub-sample, but its effects were opposite from what one would expect. If packers were using market power to gain an unfair advantage over producers, one would expect market power to lead to lower farm prices and/or higher farm-to-wholesale spreads. However, in our results, increasing HHI was associated with higher farm prices and lower farm-to-wholesale spreads. This type of unexpected result is common in other studies of market concentration's effects on livestock markets.

While the estimated HHI effect is counter-intuitive, it is also small. As we move from the smallest HHI to the largest HHI, the farm-wholesale spread drops by less than 1 cent. This drop in the farm-wholesale spread translates into a 2-cents-per-pound increase in the live price of choice cattle; retail and wholesale prices are basically unaffected by the HHI. The large amount of data in the asymmetric model make it able to measure relatively small effects with great accuracy. The small measured effect of the HHI is very statistically significant even though it has little practical effect.

There are a number of reasons why the HHI could give this counter-intuitive result. Market concentration may be driven in part by economies of size. Farm-to-wholesale spreads could be dropping as concentration rises because some part of the cost-savings from larger slaughter operations are shared with producers. Also, the HHI may not be the most appropriate measure of market power. There is a difference between the ability to exercise market power, for example, concentration, and the actual exercise of market power (Jones, Purcell, Driscoll, and Peterson, 1996). The HHI is meant to measure the ability to exercise market power. It is generally assumed in the literature that the exercise of market power by an industrial organization is reliably related to the ability to exercise it. The reality may be more complex.
