DEVELOPING AN INTEGRATED INFORMATION SYSTEM FOR THE FOOD SECTOR. By Alden Manchester, Commodity Economics Division, Economic Research Service, U.S. Department of Agriculture. Agricultural Economic Report No. 575.

ABSTRACT

An information system for the food sector which integrates measures of prices, quantities, and values provides more information about many developments in the food sector than a system that separately measures prices, quantities, or values. The author has developed such an integrated information system. His system allows greater understanding of the sources of food, outlets, food purchasers, and productivity in food marketing.

Keywords: Food expenditures, food sales, food prices.

Additional copies of this report . . .

can be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. Ask for Developing an Integrated Information System for the Food Sector (AER-575). Write to the above address for price and ordering instructions. For faster service, call the GPO order desk at 202-783-3238 and charge your purchase to your Visa, MasterCard, Choice, or GPO Deposit Account. A 25-percent bulk discount is available on orders of 100 or more copies shipped to a single address. Please add 25 percent extra for postage for shipments to foreign addresses.

Microfiche copies (\$6.50 for each report plus \$3 per order for processing) can be purchased from the order desk, National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161. Enclose check or money order, payable to NTIS. For faster service, call NTIS at 703-487-4650 and charge your purchase to your Visa, MasterCard, American Express, or NTIS Deposit Account. NTIS will ship rush orders within 24 hours for an extra \$10; charge your rush order by calling 800-336-4700.

The Economic Research Service has no copies for free mailing.

SUMMARY

An information system for the food sector which integrates measures of prices, quantities, and values provides more information about many developments in the food sector than a system that separately measures prices, quantities, or values. The author has developed such an integrated information system. His system allows greater understanding of the sources of food, outlets, food purchasers, and productivity in food marketing.

The concept of an information system which integrates price, quantity, and value is hardly novel. But in the area of food prices, consumption, and expenditures, such a system has not been available. This study contributes to such a data and analytical system. Better data at many points would clearly provide improved measures. But, some highly useful analyses are possible with available data.

The origin of food can be explained and expenditures divided between sales from farms, home production, imports, and U.S. fisheries. Total food expenditures can be divided into manufactured products and fresh foods. The question of who pays for the food can be answered, with the portions financed by governments, businesses, consumers, and others indicated. Thus, we can make more refined comparisons of income and expenditures than have been possible.

The data set permits better measures of who gets what for all food, indicating how much goes to farmers and fishermen and to the marketing system. The outlets for both offpremise and away-from-home food are a basic part of the information system and can be measured both in dollars and in quantities.

Alternative measures of both food quantities and prices become available with this information system. These measures permit the integration of price, quantity, and value in a consistent fashion and provide measures of expenditures by food groups which are consistent with the totals both of prices and quantities.

Here are some of the principal findings of the author's analysis:

- o Food expenditures by families and individuals were 14.5 percent of disposable personal income in 1985, down from 28.3 percent in 1921 and 60.6 percent in 1869.
- o Food produced and consumed at home was 3 percent of all food consumed in 1985, compared with about 33 percent in 1869.
- o Food stores, including supermarkets, sell 91 percent of food for home consumption; supermarkets alone sell 61 percent of all food for home consumption.
- o Restaurants account for 40 percent of sales of food for away-from-home consumption, while fast food places account for 30 percent, schools and colleges 10 percent, and hotels and motels 5 percent.
- o Labor productivity in food marketing increased from 1960 to 1972, declined between 1972 and 1980, and then rose slightly in 1981-82.

Developing an Integrated Information System for the Food Sector

Alden Manchester *

INTRODUCTION

A complete data and information system for the farm sector and its major subsectors has existed for many years. It has been updated and improved many times in the past half century. The data and information system for the food sector beyond the farm has received somewhat less attention.

A data system consists of the numbers and other factual data describing the sector or subsector of the economy that is of interest. An information system further embodies the analytical tools that are employed in making use of the data in decisionmaking. Furthermore, data are of at least two types; numbers and other facts are either simple or complex. Simple numbers are those that can be directly observed and reported, such as acres in corn and bushels produced. A complex number is an economic abstraction which is the result of a more elaborate analytical framework embodying a conceptual framework and informed judgment as to the appropriate coefficients. The estimation of farm income is perhaps the best example of how complex such a number really is. In principle, many such phenomena could be observed directly (for example, the incomes of farmers), but that would not make complex numbers into simple numbers; it would merely push the complexity back into each farmer's accounting system where it would become a "black box" whose workings are inscrutable to the observer.

A fundamental identity is that

$$\text{price} \times \text{quantity} = \text{value}.$$

Quantity measures for most foods were developed years ago for use in situation and outlook analysis. The basic tool is the supply-and-use table which employs data on production, stocks, foreign trade, and nonfood use to derive estimates of domestic disappearance for food use. Until the eighties, such data were available for 250 foods, including all significant items (Manchester and Farrell, 1981).

Price data, mainly from the Bureau of Labor Statistics (BLS), U.S. Department of Labor, for a sample of foods bought by consumers have been available longer than quantity data. The price data, however, are of a specific type consistent with their intended use in constructing indexes of pure price

*The author is senior economist in the Commodity Economics Division, Economic Research Service, U.S. Department of Agriculture.

change. Thus, one cannot insert these prices in the above identity and derive an estimate of the value of all of the beef purchased by U.S. consumers, for example. Measures of average prices are needed.

The value figure is expenditures for food in the United States. We can derive that figure independently of prices and quantities by several methods. The challenge is to develop a system which integrates prices, quantities, and expenditures. This report describes such an integrated system and several analytical uses.

Figure 1 provides an overview of the U.S. food system. Americans spent \$347 billion for food in 1982 and another \$55 billion for alcoholic beverages. Most of this \$402 billion was paid for by families and individuals, but a portion was produced and consumed at home with relatively little cash outlay. Governments and businesses paid for part of the food. In these circumstances, we must determine what portion of food expenditures is incurred by each of these groups in order to make a meaningful comparison of food expenditures and incomes.

The share of food dollars going for away-from-home meals and snacks has been increasing for more than a century, but because restaurant meals include many more services than food purchased at the grocery store, the shares of value and quantity of food away from home are quite different.

Supermarkets now make 61 percent of the sales for home use, compared with 6 percent in 1939. Fast food places account for 30 percent of all away-from-home food sales, up from 7 percent in 1939.

As farming has moved more and more into the industrialized economy, the contribution of farming to the value of food consumed has become smaller. The shares of farm input suppliers, processors, wholesalers, and retailers have increased. The share of restaurants and other away-from-home eating places, in particular, has risen sharply.

These and many other questions can be investigated using data on food expenditures. Several methods of measuring food expenditures are discussed in this report. In an ideal world where accurate data would be available on all economic activities, measuring food expenditures by each of the methods would yield identical results. In the imperfect real world, the degree to which measurements by each of the methods agree gives some indication of the confidence one can have in the results. In addition, each of the methods provides information on different aspects of the system.

There is no single right or best measure for all purposes. One measure is often more appropriate than another for a specific use. If complete, ideal data were available and if calculation was costless, the analyst should generate a new measure for each problem. But data are neither complete nor ideal and computation is not costless. This report presents a variety of measures wherever possible in order to broaden the analyst's range of choices. The information provided by each method is then used to describe certain aspects of the food production and marketing system. (See Manchester and King, 1979, for the early development of this food expenditure series.)

Figure 1
Food sector flows, 1982¹

Supply 2/

Utilization

Consumption

Food furnished 8.1 percent		Household purchases 84.8 percent		Business purchases 4.0 percent		Home production 3.1 percent	
Meals 6.1 percent	Public programs 2.0 percent	Foods 68.0 percent	Meals 16.8 percent	Meals 4.0 percent 5 /		Farm 0.6 percent	Nonfarm 2.5 percent
Marketed 96.9 percent						Not Marketed 3.1 percent	
U.S. food consumption 100.0 percent							

1/ Percentage of U.S. food consumption. 2/ Total supply is 115.3 percent of domestic consumption.

3/ includes sport fish and game and farm and nonfarm home production. 4/ Excludes use for feed and seed.

5/ Business expenses for travel accounts and entertainment.

MEASUREMENT: CONCEPTS AND APPROACHES

There are three basic methods of measuring food expenditures and some variations:

- o Retail sales,
- o Commodity flow or value added, and
- o Value of quantities at retail prices.

For many purposes, measuring sales is the preferred method. The aggregate that one wishes to measure is the total purchases of food for offpremise use, meals and snacks, and alcoholic beverages by families, individuals, and institutions. To the extent that data are available, sales provide the most direct measurement of food expenditures.

The commodity-flow or value-added method builds up from the value of food products produced by farmers, imported, or caught by fishermen, adding the margins of each successive stage. These stages include processing, wholesaling, retailing, and food service. This method provides values by commodity groups which are not available by the sales method.

Value at retail selling prices starts from the identity mentioned earlier: price x quantity = value. Quantities of individual foods are valued at average retail selling prices and the total value determined. Because the only available prices for individual commodities are for retail stores, the additional margin for food service must be determined separately and added.

Constraints of Data Availability

Some data needed for each of these measurement methods are unavailable. Thus, the methods that one can use for any particular year are determined by data availability. Data tend to become increasingly available over time, although the increasing cost of obtaining statistical information and declining budgets exert a somewhat contrary influence.

Retail Sales

Data on retail sales by type of store are the product of the Bureau of the Census, U.S. Department of Commerce. They first became available from the 1929 Census. Since then, censuses have been taken in 1933, 1935, 1937, 1939, 1948, 1954, 1958, 1963, 1967, 1972, 1977, and 1982. Since 1951, the monthly and annual retail trade reports have provided current estimates by type of store from a sample of retail stores. The Bureau of Economic Analysis (BEA), U.S. Department of Commerce, has estimated annual sales from 1929 to 1950 and smoothed out some of the rough spots in the series since then. From 1965 through 1981, monthly selected service receipts provided data for hotels, motels, tourist courts, motion picture theaters, and bowling alleys. The monthly data have now been replaced by an annual survey with broadened coverage.

Information on how much food, alcoholic beverages, and meals and snacks are sold by different types of stores is generally available only from the censuses roughly every 5 years. Data for other years must be interpolated. The exception is grocery stores, for which an annual series is available from Supermarket Business magazine. The census figure for food sales by grocery stores is unusable because it did not change significantly for 25 years, while

the supermarket revolution transformed the sales of supermarkets and grocery stores. Until the advent of the electronic cash register, food store operators had no way of determining how much of their sales of groceries consisted of food products and how much was soap, detergents, paper towels, and other nonfood grocery products. Under these circumstances, grocery store operators have provided the Bureau of the Census with their best guesses, which did not change for many years. In fact, we get the anomalous situation that nonfood sales declined to accommodate an increase in sales of beer and wine during 1963-77. The Supermarket Business figures, on the other hand, are based on records from a limited number of stores on the sales of several hundred categories of foods and nonfoods. These reports have had the advantage of providing annual data on a consistent basis since 1947. One would prefer a larger sample as a base, but no such series is available (table 1).

Data from current retail trade and services reports of the Bureau of the Census provided the basis for 92 percent of expenditures for offpremise food and 73 percent of meals and snacks in 1980.

Quantities

The basic quantity information on food comes from supply-utilization data of the Economic Research Service. For basic commodities, this information is available since 1910. Annual data are available for all products and quarterly data for animal products and some crops. (For a more detailed discussion of these data, including a list of products, see Manchester and Farrell, 1981.)

The supply-use tables are mostly for farm-level products, although many are for consumer products, such as canned and frozen fruits and vegetables, individual manufactured dairy products, and others. Those for products such as flour and refined sugar include both final use and use in manufacturing other food products.

Table 1--Distribution of grocery store sales

Year	Food		Alcoholic beverages		Other nonfood	
	Census : of Retail : Trade	Supermarket : Business	Census : of Retail : Trade	Supermarket : Business	Census : of Retail : Trade	Supermarket : Business
	<u>Percent</u>					
1963	84.5	76.5	1.5	4.9	14.0	18.6
1967	85.0	73.4	1.7	4.9	13.3	21.7
1972	84.9	73.1	2.1	5.4	13.0	21.5
1977	84.9	72.6	2.5	5.1	12.6	22.3
1982	78.2	71.7	3.3	5.5	18.5	22.8

Information on quantity and value of manufactured food products is available from the Census of Manufactures every 5 years for nearly all foods. Some, such as soup, are concealed in larger aggregates in order to preclude disclosure of the operations of dominant manufacturers. Information on production of manufactured dairy products is available from the National Agricultural Statistics Service (NASS), U.S. Department of Agriculture (USDA). Current quantity information on flour and fats and oils is provided monthly by the Bureau of the Census. NASS also provides data on utilization of potatoes, peanuts, and most fruits and vegetables. Data on purchases of individual foods by food service firms is supplied only in two surveys (Van Dress, 1971 and 1982).

The annual survey of manufactures by the Bureau of the Census provides value data on shipments of classes of food products. The Census of Manufactures is used as a base every 5 years, and annual figures are obtained from a sample of manufacturers. No effort has been made to revise the series when a new Census of Manufactures is taken, and the change from a noncensus year to a census year, from 1971 to 1972 for example, is sometimes unbelievable.

Retail Prices

The principal source of data on retail price movements is the Bureau of Labor Statistics (BLS). Since 1890, BLS has published retail price indexes plus some retail price information. Beginning in 1978, coverage was expanded to the entire urban portion of the country. Before then, only prices paid by clerical and manual workers in cities were represented. Through 1977, BLS collected prices for a sample of individual food products that were fairly narrowly defined with detailed specifications for each product. Since that time, the indexes reflect a broader coverage of food products, but the component price in each store is still for a narrowly specified product.

NASS and predecessor agencies collected prices paid by farmers for individual food products from 1910 to 1976. These prices were for products usually purchased by farmers in a particular store, not for the narrowly defined products priced by BLS.

From BLS and formerly from NASS, good information is available on price movements in the form of indexes. The information on price levels from these sources is much less satisfactory because it is not designed to provide such data. One must turn to other sources to determine the average level of prices for all purchases. The primary source of such data is the periodic surveys of food consumption and purchases conducted by USDA since the mid-1930's. From the quantity and value data provided for individual products in these surveys, imputed average prices have been calculated. David Smallwood has calculated such average prices for purchased foods in the 1977-78 Nationwide Food Consumption Survey. Corinne LeBovit had earlier calculated similar prices from the spring portion of the 1965-66 Household Food Consumption Survey.

Farm Prices

NASS has collected and published prices received by farmers for most food products for many years. Such prices are available for most products since 1910 and for major crops well into the 19th century. These are average prices for all of a given product, so that the prices of cattle, for instance, include both cattle going to slaughter and those going to the feedlot. Sorting out the food portion necessitates the use of other data, in this case prices from market news.

Manufacturers' Prices

Implicit average selling or transfer prices of manufacturers of food products for individual products and product groups can be calculated from the Census of Manufactures data on quantity and value.

Valuation Problems

An analyst can measure the value of foods at the manufacturer, farm, and retail levels for most foods, using the quantity and price data available. But for at least three categories, this measurement is not straightforward.

Most food consumed in the United States was once produced at home. Although much less important than a century ago, measuring home production is still a problem. What is the appropriate level at which to value home-produced food? In estimating farm income; the appropriate level is the price at which a food could have been sold if the farmer had chosen to sell it rather than to eat it at home. Primarily for comparison with other sources of food, however, the value of food produced and consumed on farms and in nonfarm households (mainly home gardens) is estimated here at retail prices in the stores in the immediate area, as is done in the Nationwide Food Consumption Survey.

A different kind of problem arises where the sale is of a product combining food and other goods and services. In hospitals, nursing homes, boarding houses, and other institutions, food is not priced separately. Only a relatively small portion of the hospital room rate is for food, but there is no way of determining what it is. The choice then is between valuing such food at the cost to the hospital or other institution or at estimated restaurant prices. The food expenditure series values it at cost, because that is the last point at which a separate transaction for food is observed.

Somewhat similar problems are encountered in the case of food furnished as pay to employees in restaurants and institutions or supplied to inmates in prisons. Again, the choice has been made to value these at cost to the institution in the basic series.

What Has Been Measured

Data are available to estimate food expenditures on the basis of retail sales since 1929. Expenditures for food since 1869 can be estimated by the commodity-flow method for census years with interpolations for the intervening years. The basic food expenditure series was calculated by use of retail sales beginning in 1929. From 1869 to 1929, the commodity-flow method was used. There were some differences in the 1929 estimates, and the figures resulting from the commodity-flow procedure for the earlier years were modified so the totals were equal in 1929. Figures are available for 1869, 1879, and annually since 1889. The annual interpolations between census years were based on data developed by Barger (1955) and Shaw (1947).

Value of foods at retail store prices has been estimated for selected years since 1940. The data for such a calculation are available for all years since 1935. If the problem of determining average price levels could be satisfactorily resolved for earlier years, these calculations could be extended back to 1910. We can annually estimate the additional margins of food service establishments since 1953, when the Bureau of Labor Statistics

began collecting and publishing prices for food away from home. Before that date, only the data from the Census of Business were available.

MEASUREMENT: COMPARISONS

The basic series shows food expenditures rising from \$3.6 billion in 1869 to \$24 billion in 1929, \$74 billion in 1960, and \$411 billion in 1985 (table 2). Away-from-home meals and snacks rose from 5 percent of the total in 1869 to 43 percent in 1985. Home production declined from 33 percent of the total in 1869 to 2 percent in 1985.

Value at Retail Store Prices

Valuing all food at retail store prices provides a very useful analytical tool. Several uses to which it can be put, such as determining the origin of food supplies and measuring marketing services, are discussed in this report.

For such a measure, food which is valued at other levels in the basic expenditure series must be revalued to retail store price levels. This calculation involves some additions from lower price levels (such as manufacturers' sales to consumers) and a number of deductions for higher levels (such as restaurant sales). The base year for this measure is 1977. Using the commodity-flow method and data from the Censuses of Business and Manufactures for 1977, the following measures of prices at various levels were obtained:

Percentage of retail store prices, 1977

Manufacturers* and shippers* selling prices	68.83
Buying prices of food service	78.61
Retail store prices	100.00
Restaurant prices	167.10

The base for measurement is the sales by manufacturers and shippers of fresh products (fresh fruits, vegetables, and shell eggs) at their selling prices (table 3). These prices are assumed to be the same both for sales to retail stores and to food service organizations. Although this assumption is probably not exactly true because of differences in package size and composition of products, the differences may well be nearly offsetting. Restaurants and institutions buy many products in larger containers than do households, but offsetting that, they buy others in individual serving packets at considerably higher prices.

The only required adjustments to expenditures for offpremise consumption are adjustments to sales by manufacturers and wholesalers to consumers and USDA donations of commodities to families. These transactions are revalued to the retail store price level by adding 27.2 percent in 1977 ($100.00/78.61 = 1.272$) and a comparable amount in other years, the exact amount depending on the relative movement of the price indexes.

Table 2--Expenditures for food and alcoholic beverages

Year	Food for offpremise use			Meals and snacks			All food	Alcoholic beverages

Table 3--Sales and margins for consumer food by commodity-flow method, 1977--Continued

Type of seller	Total sales 1 /	Sales at manufacturers' prices 2/	Wholesale margin 3 /	Sales at wholesale prices	Retail margin 4 /	Retail sales	Sales taxes and tips	Total
<u>Million dollars</u>								
Sales through food service establishments:								
Manufacturers and shippers		8,480	0	8,480	--	--	--	--
Merchant whole- salers and assemblers		16,210	2,433	18,613	--	--	--	--
Agents and brokers		2,999	800	3,799	--	--	--	--
Sales branches and offices		4,642	561	5,203	--	--	--	--
All whole- salers		23,851	3,794	27,645	--	--	--	--
Retail stores		649	6/ 267	916	--	--	--	--
Total		32,980	4,061	37,041	41,770	78,811	6,655	85,466

-- = Not calculated until a later point.

1/ Food and kindred products, excluding pet food, animal feed, alcoholic beverages, ice, food and feed materials, and byproducts.

2/ Sales at manufacturers' or shippers' prices plus transportation. Distribution of sales from Census, Sales by Class of Customer.

3/ Basic data from 1977 Census of Wholesale Trade, vol. 1, part 3. Includes margins of more than one wholesaler in some cases.

4/ Basic data from annual retail trade report, Bur. of the Census. Markup in institutions assumed same as eating places.

5/ Includes wholesalers' and warehouse margins.

6/ Includes wholesalers', warehouse, and store margins.

All expenditures for meals and snacks must be adjusted. The additional sales taxes, due to higher average rates on restaurant meals than on store sales of food, are subtracted. Tips are also subtracted. Net sales are then total sales, plus the value of child-nutrition subsidies, less tips, less additional sales taxes. Net sales were reduced by 40.2 percent in 1977, 37.0 percent in 1967, and comparable amounts in other years, depending on the movement of the price indexes. Food supplied by institutions and employers is valued in the basic series at its purchase price, so 27.2 percent is added in 1977 and 27.0 percent in 1967 to estimate the value of food supplied at retail store prices.

Prices at the four levels do not move in exactly the same way. Year-to-year changes are different and there are long-term trends in margins (fig. 2). (The margins are indicated by these calculated indexes of prices at four levels as a percentage of retail store prices.) The accumulated margins between the manufacturer and shipper level and retail stores have varied, but no long-term trend is evident. On the other hand, restaurant margins have risen fairly consistently since 1929.

Results of these calculations for selected years since 1929 are shown in table 4. The figures for offpremise use are only a little different from those in the basic series because the adjustments apply to a small component, but the figure for meals and snacks rises more slowly because the effects of the increasing margin shown in figure 1 are eliminated.

The other method of estimating the value at retail store prices starts with the quantity of food in retail weight multiplied by retail prices to derive a value. (See Heien, 1983, for use of a similar measure.) Most of the food products for which ERS regularly prepares supply-utilization tables are for products fairly near the farm level. Many are for first-generation manufactured products, such as flour, canned milk, refined sugar, margarine, shortening, and frozen vegetables. None of the ERS tables are for second-generation products, the comminuted products that combine a number of

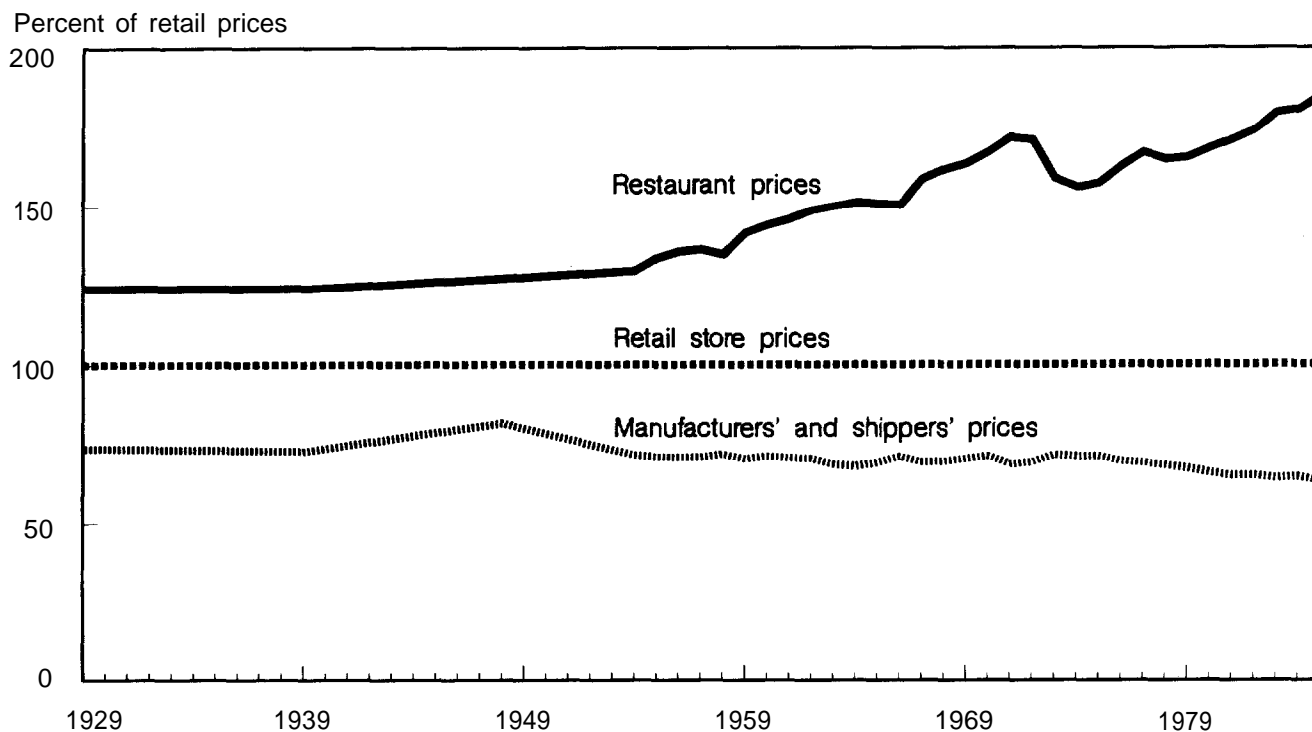

Table 4--Food expenditures at retail store prices from sales and markups

Year	Food for offpremise use			Meals and snacks	All food
	Sales and donations	Home production	Total		
	<u>Million dollars</u>				
1929	15,469	4,558	20,027	3,500	23,527
1939	12,011	3,270	15,281	3,113	18,394
1948	31,942	6,706	38,648	10,067	48,715
1954	40,314	5,642	45,956	12,977	58,933
1960	49,763	4,597	54,360	14,795	69,155
1970	74,049	3,811	77,860	25,881	103,741
1977	131,203	6,002	137,205	53,289	190,494
1980	178,363	8,195	186,558	75,071	261,629
1985	227,608	6,860	234,468	101,610	336,078

Note: See app. table 6 for annual data.

Relative prices of food at three stages of the system

Source: App. table 5.

ingredients. 1/ A substantial part of the value of some agricultural products is involved in these comminuted foods, about a third of total value. Most of the value for grains, sweeteners, and fats and oils comes from comminuted products.

For each commodity or commodity group for which ERS maintains supply-utilization data, total disappearance for domestic sales (omitting products produced and consumed on the same farm) is divided among the main products and each of the comminuted product groups. The basic data come from the tables of the Census of Manufactures for 1967, 1977, and 1982 on materials used. The total value at retail store prices is allocated to the materials shown, so some minor ingredients are ignored.

The simplest product group is fish, for which the Census of Manufactures shows no use in other products. Thus, we assumed that all fish products are sold as seafood and are priced accordingly.

1/ Comminuted products are those combining several ingredients where no original product is dominant; for example, baked goods, confectionery products, soups, and frozen dinners.

The most complicated product group is sweeteners. Their use is reported by 13 other industries. The retail store value of each of these other product groups is allocated among sweeteners and the other products used in their manufacture in proportion to the relative value of the sweeteners used in each of the other product groups. For example, 17.1 percent of the value of food materials used in bakery products consisted of sweeteners in 1977, so 17.1 percent of the 18.8 billion dollars' worth of bakery products (at retail store prices) is allocated to sweeteners. In total, 5.8 billion dollars' worth of sugar and other sweeteners was sold through retail stores or food service, and another 22 billion dollars' worth of sweeteners was used in other products (table 5).

Sales through retail stores and food service are valued at 1977 average prices, which come from the 1977-78 Nationwide Food Consumption Survey (USDA, HNIC) adjusted to calendar year 1977 by use of BLS price indexes. The total value of each of the comminuted products is derived from quantity shipments in the Census of Manufactures and similar 1977 average prices.

Table 5--Value at retail store prices of food marketed, 1977

Farm-product group	Value at retail store prices		
	Original product 1/	In comminuted products 2/	Total sales 3/
	Million dollars		
Meat	41,709	2,378	44,087
Fish	4,508	0	4,508
Poultry and eggs	11,756	3,596	15,352
Milk	22,435	1,412	23,847
Fruits, vegetables, and nuts	28,132	9,185	37,317
Grains	1,535	13,771	15,306
Sweeteners	5,783	22,016	27,799
Fats and oils	3,167	8,743	11,910
Other 4/	6,278	6,545	12,823
Total	125,303	67,646	192,949

1/ All uses where the original product is still identifiable; includes fresh, canned, frozen, and dried.

2/ Comminuted products are those combining several ingredients where no original product is dominant; for example, baked goods, confectioneries, soups, and frozen dinners.

3/ Omitting home production and sales taxes.

4/ Herbs, spices, cocoa, popcorn, mint, chicle, yeast, oils and flavors, coffee, and tea.

The total value at retail store prices (including home consumption) in 1977 was \$201,521 million (table 6). This compares with \$190,494 million calculated from food expenditures (table 4), a 5.8-percent difference.

Over half of the difference is traceable. Several factors whose effects are not considered in the annual estimates affect the totals:

Value at retail store prices (from prices and quantities). 1977

	<u>Million dollars</u>
Total, unadjusted (table 6)	201,521
Less: Exports and shipments to territories of comminuted products	-1,008
Change in wholesalers* and retailers' stocks	- 849
Shrinkage	-4,812
Plus: Higher prices in Alaska and Hawaii	<u>+ 263</u>
Total, adjusted	195,079

The adjusted total is 2.4 percent greater than the \$190,494 million estimated from sales and markups. Most of the difference is due to shrinkage in the marketing channels not otherwise accounted for and to exports and shipments to Puerto Rico, Guam, and Samoa of comminuted products whose value was included in the calculations because these products are not included in the supply-utilization tables. This shrinkage is estimated at 2.4 percent (Pierson and others, 1982). Changes in stocks of wholesalers and retailers more than

Table 6--Two measures of value of food at retail store prices,
including home-produced foods

Year	From sales and markups	From prices and quantities	Difference
	- - - <u>Million dollars</u> - - -		<u>Percent</u>
1960	69,155	74,157	7.2
1965	76,668	84,415	10.1
1970	103,741	111,927	7.9
1975	166,358	181,065	8.8
1977	190,494	201,521	5.8
1980	261,629	278,411	6.4
1983	307,669	324,240	5.4

Note: See app. table 6 for annual data.

offset the effects of higher retail store prices in Alaska and Hawaii than elsewhere in the country. The basic Nationwide Food Consumption Survey that provided the average prices did not include Alaska and Hawaii (USDA, HNIC). The difference shown here is based on supplementary surveys in Alaska and Hawaii. Over the years, the two measures have not moved exactly together; the difference has been as great as 10 percent (table 6).

Commodity-Flow Method

BEA's input-output analysis is an application of the commodity-flow method. The flows of commodities through the system are followed from farm to manufacturer and then through transportation, wholesaling, retailing, and food service, with appropriate margins added at each level. The input-output analysis provides the base-year data for the National Income and Product Accounts. BEA conducts this analysis for each year of the Economic Censuses (USDC, BEA).

The food category in input-output analyses (and also in personal consumption expenditures) must be adjusted by removing those items which are not human food to obtain a measure comparable to that in this food expenditure series. This adjustment involves separating pet food, animal feed (primarily for horses), and ice (appendix table 18).

Food expenditures as estimated by the commodity-flow method in the input-output analysis were significantly higher than those estimated primarily from retail sales in 1963, 1967, 1972, and 1977 (table 7). The big differences are in food purchased for offpremise consumption. The input-output results are 14 percent higher in 1963, 21 percent higher in 1967, 18 percent higher in 1972, and 19 percent higher in 1977.

Those differences are not from the estimated margins in wholesaling and retailing. In 1977, these margins added 45.5 percent to the value of foods at the prices of manufacturers and shippers (plus transportation) in the input-output analysis. Comparable margins for the expenditure series were 44.9 percent. The lower margins of the food expenditure series would reduce total expenditures by 0.4 percent.

These large differences apparently are not caused by assigning a substantially larger share of food products produced by manufacturers or sold by shippers to consumer foods rather than to intermediate products to be used by other manufacturers. The value of intermediate uses of the products of the food and kindred products industry other than in eating and drinking places was \$50,401 million in the 1977 input-output analysis and \$49,283 million from the Census of Manufactures (table 15). Imports of intermediate products totaled at least \$1 billion. Because the tables of the Census of Manufactures on materials used provide nearly all of the information on sales of intermediate food products to other manufacturers, their completeness becomes a major consideration. Manufacturers are asked to report only the quantity and value of major products used. All products which are minor to that industry are reported simply as other materials and supplies. The rules of thumb by which the all-other amounts are distributed thus become important, but they do not appear to cause the differences.

In the numerous checks and balances built into a commodity-flow estimating procedure, a figure derived from retail sales is logically employed. If one uses the Census of Retail Trade merchandise line sales for grocery stores,

-- = Not available.

1/ Excludes home production and USDA donations to families.

2/ At purchaser's prices, excluding pet food, animal feed, and ice. Food used by others estimated by ERS from producers' value.

3/ Excludes firewood. Valued at farm prices.

4/ Includes education, hospitals, institutions, recreational places, railroads, and airlines.

rather than the Supermarket Business figures (table 1), grocery store sales of food are substantially larger than in the food expenditure series, but that does not account for all of the difference.

	<u>Difference in grocery store sales of food</u>	<u>Difference in offpremise sales</u>
	<u>Million dollars</u>	
1963	4,204	7,463
1967	7,476	12,398
1972	10,949	15,070
1977	18,159	24,772

The difference in grocery store sales was 56 percent of the overall difference in 1963, increasing to 60 percent in 1967 and 73 percent in 1972 and 1977.

George Jaszi, BEA director for 23 years, recognizes the problem caused by using retail store sales as the mover for estimates of food expenditures in the early 1970's (Jaszi, 1986, p. 414). Estimated food expenditures rose with total sales of grocery stores, even though much of the increase was in nonfoods. However, the benchmark estimates from the input-output analysis are also affected by overstatement of food sales in grocery stores.

Measures of Price

Price indexes for food and its at-home and away-from-home components are available from BLS and from the National Income and Product Accounts of BEA. Two additional measures were prepared in this study.

The BLS indexes use fixed weights which are revised approximately every 10 years. The implicit deflator for personal consumption expenditures for food (the GNP deflator) is calculated by dividing current food expenditures by those at fixed retail store prices. The latter are calculated using BLS price indexes for major food groups and the ERS consumer expenditure figures from the marketing bill plus fish and imports as weights.

A link-and-chain price index was constructed by calculating a link index for each pair of years by use of the first year's quantities (disappearance for domestic consumption) as weights. These indexes of year-to-year change in price are then chained together with 1977 as the base year (table 8, line 6). This index includes both the effects of annually changing weights and the effects of change in average price for each product between 1967 and 1977. It also includes the effects of changes in the uses of products such as flour, sugar, and fats and oils between 1967 and 1977 and between 1977 and 1982. For food at home, the resulting link-and-chain price index rose somewhat more between 1960 and 1984 than the BLS index or the GNP deflator, 243 percent compared with 227 percent for the BLS index and 222 percent for the GNP deflator. Allowing for changes before 1967 would increase this disparity. Most of the difference between the BLS index and this link-and-chain index are probably due to changes in the mix of package sizes, qualities, and brands, and changes in use. In a comparison of 42 foods, Lamm (1980) constructed

fixed-weight (Laspeyres) and changing-weight (Paasche) indexes for 1964-77 and found them generally similar.

Using this link-and-chain price index, we adjusted expenditures at retail store prices (table 4) to 1977 price levels. Sales of meals and snacks at 1977 retail store prices were adjusted by adding the purchases of food for institutions, which are valued at less than restaurant prices, all at 1977 levels. This adjustment provided an estimate of total food expenditures at 1977 prices. I calculated the implicit deflator by dividing food expenditures at current prices by food expenditures at 1977 prices (table 8, line 3). These calculations indicate that the prices of all food rose 240 percent during 1960-84, compared with 244 percent by the BLS index and 239 percent by the GNP deflator.

Measures of Quantity

The interrelationships of price, quantity, and value that were discussed earlier lead to a variety of measures of food consumption. One can add up the pounds of beef, oranges, and flour at various levels in the marketing system. But this approach takes a pound of scallops at \$7 equal to a pound of flour at 25 cents. The ERS index of per capita food consumption deals with these problems by using fixed price weights, changing the weights every 10 years. Other approaches use price indexes to deflate the value figures for food expenditures.

ERS measures consumption (disappearance) both in primary distribution weight and in retail weight. Primary distribution weight is usually the weight as manufactured for processed products and quantities produced for fresh

Table 8--Food prices by eight measures

Measure	1960	1965	1970	1975	1980	1984
				<u>1977 = 100</u>		
All food:						
BLS	45.8	49.1	59.8	91.3	132.5	157.6
GNP deflator	46.7	49.3	61.8	93.6	131.4	157.4
Food expenditures deflator	45.0	47.9	58.1	93.4	133.2	149.0
Food at home:						
BLS	47.1	50.2	59.8	92.4	132.2	153.8
GNP deflator	48.4	51.9	62.3	95.7	131.0	154.7
Link-and-chain	43.6	46.3	55.4	93.0	131.4	149.6
Food away-from-home:						
BLS	40.6	45.4	59.9	87.0	133.3	159.7
GNP deflator	41.1	45.9	60.5	87.7	132.4	165.2

Note: See app. table 7 for annual data.

products, but there are many variations. Retail weight is an estimate of the weight as sold in retail stores. For most processed products, it is the same as primary distribution weight. For meats, there are substantial changes in going from carcass weight (the primary distribution weight) to retail cuts.

There are varying amounts of inedible matter in different foods: bones in meat and poultry, pits in peaches, cores in apples, and shells on peanuts. Measuring edible weight eliminates the average amount of inedible materials from each category. The conversion factors are taken from Adams (1975).

But these adjustments do not solve all the problems. A number of products are reconstituted before they are used, such as potato flakes, dried milk, and evaporated milk. Coffee and tea present a special problem. Other beverages--milk, soft drinks, fruit juices--are measured as liquids. In the retail weight measure, coffee is beans and tea is leaves. When the water is added, they make many times more beverage. In order to provide comparable measures for beverages of different kinds, coffee and tea are here calculated in liquid form. Of course, when one does this, beverages play a much more important part in the totals.

The way in which different products are handled, especially beverages, greatly affects the results (table 9). Total consumption on an edible weight basis generally has increased since 1910. If only the solid foods are included, consumption declined. The meat figures are particularly sensitive to the stages of the beef and pork cycles in each of these years. Omitting soft drinks from the retail weight figures, as is usually done, shows a decline over these 70 years, but including soft drinks indicates increased per capita consumption. The price-weighted index behaves somewhat differently than the retail weight figures. That index assumes no change in the product mix made from each of the basic commodities, such as flour or fats and oils, for at least 10-year periods.

Another method of estimating change in quantity is by deflating food expenditures. The simplest method of deflating food expenditures is to use the BLS food price indexes. Because the difference between away-from-home and at-home food prices has already been allowed for in calculating expenditures at retail food store prices, a straightforward method is to deflate expenditures at retail food store prices by the BLS price index for food at home. Thus, quantity weights in the price index are fixed for approximately 10-year periods. A link-and-chain index was constructed to allow for yearly changes in quantities of individual foods or food groups and to reflect those changes as well as price changes in the index. Total food expenditures at retail store prices were deflated using this index. Comparisons of the eight indexes are shown in table 10.

The simplest measure--pounds of food, including soft drinks--increased 10 percent from 1960 to 1983. The price-weighted indexes give some evidence of the effects of the particular method of weighting which is selected. If one uses 1967-69 prices as weights, the index increases 13.6 percent from 1960 to 1983. If 1977 prices are used as weights, the increase is 13.9 percent. Changing weights each decade gives an increase of 11.1 percent. The pattern in intervening years is quite different. Use of price weights gives meat, poultry, and fish much more importance than they would have if pounds were used, and fresh fruits and vegetables and sweeteners are less important (table 11). The choice of the time period for the weights also makes quite a bit of difference (table 10).

Table 9--Various measures of per capita consumption of food

Year	Price-weighted index	Retail weight : (civilian) : Edible weight (civilian and military).					All other foods	Total
		Excluding soft drinks	Including soft drinks	Coffee, tea, soft drinks	Fluid milk products, fruit juices			
	1967=100	Pounds						
1910	84.0	1,589	1,598	277	290	1,086	1,653

BLS food-at-home price index	95.0	95.5	99.0	97.1	101.5	101.7	7.1
GNP deflator	88.3	89.4	93.5	93.8	102.4	103.4	17.1
Link-and-chain price index	91.5	94.1	99.2	93.7	100.7	104.7	14.4

Note: See app. table 8 for annual data.

1/ Through 1965, 1957-59 prices; 1966-1975, 1967-69 prices; thereafter, 1977-79 prices.

Deflating food expenditures by four different price series provides alternative measures of changes in food quantities (table 10). The simplistic deflation of total food expenditures by the BLS all-food price index yields a 17.5-percent increase in quantities between 1960 and 1983. This measure is inappropriate because the fixed-weight BLS price index reflects the changes in food at home and food away from home and among commodity groups only at approximately 10-year intervals.

Deflating expenditures at retail food store prices by the BLS food-at-home price index indicates only a 7.1-percent increase in quantities between 1960 and 1983. This measure provides a year-by-year adjustment for the change from food at home to food away from home but only the once-a-decade adjustment for product mix.

Use of the GNP implicit price deflator for food yields a 17.1-percent increase in quantities over the period. The GNP deflator is calculated by dividing current food expenditures by those at 1982 retail store prices. The 1982 prices are calculated from BLS price indexes for major food groups weighted by ERS consumer expenditures from the marketing bill.

Deflating food expenditures at retail store prices by a link-and-chain price index which uses the previous year's prices as weights provides a 14.4-percent increase in quantities of food over the period. This calculation, while more complicated than the others, comes closest to separating price and quantity changes into their components. Yearly changes in product mix are reflected in the quantity measures and quality changes in the average price for each commodity.

Expenditures by Food Groups

The two measures of value at retail store prices make possible the calculation of expenditures by food groups. The expenditures for each food group derived from price and quantity data are adjusted to the total value at retail store

Table 11--Relative importance of selected product groups in four quantity indexes, 1981

Product group	Pounds of food	Price-weighted indexes using--		
		1967-69 prices	1977 prices	Previous year's prices
				<u>Percent</u>
Meat	9.6	24.4	22.4	23.5
Poultry	3.8	5.1	6.0	5.6
Fish	1.0	2.0	2.4	2.4
Fresh fruits and vegetables	18.7	9.5	8.2	8.1
Sweeteners	20.3	15.7	14.2	14.9

prices from prices and markups, using the same adjustment for each commodity group. The other adjustments which were made to obtain value at retail store prices from sales and markups are then reversed proportionately for each commodity group (table 12). These values are for all of the uses of each product group including both retail products and comminuted products. This calculation assumes that the distribution of each commodity group between offpremise use and food service is the same. More refined estimates can be made using survey data, but that has not been done for this study.

For the base years, 1967, 1977, and 1982, the farm product groups can be translated into consumer product groups (table 13). Between 1967 and 1982, the share of meat products in total consumer expenditures declined by 2.3 percentage points and fresh fruit and vegetables by 3.9 percentage points. Beverages had the largest gain. Expenditures reflect both price and quantity changes. In most of these cases, the biggest effect is from price change rather than quantity change. The prices of sugar, cocoa, and coffee were all high in 1977.

Table 12--Expenditures for purchased foods (excluding food produced at home),
by farm-product group

Value in	1960	1965	1967	1970	1975	1977	1980	1984

Note: See app. table 9 for annual data. These figures are for all identifiable uses of the farm product, such as grain in bakery products, cereals, soups, and other foods.

USES OF THE INFORMATION

By using the measures discussed in the preceding section, we can conduct a number of analyses. This section discusses several.

Origin of Food

Retail food prices and supply-utilization tables for all food commodities allow one to categorize the origin of food as home production, U.S. farms, or other foods (which includes fish, imports, yeast, and baking powder).

Table 13--Expenditures for purchased foods (excluding food produced at home) by consumer product group

Consumer product group	Annual sales			Share of total sales		
	1967	1977	1982	1967	1977	1982
	- - - Million dollars - - -			- - - Percent - - -

Other	: 1,712	2,360	8,554	1.9	1.1	2.5
Total	: 90,010	213,945	337,933	100.0	100.0	100.0

Note: These figures are for familiar consumer food products. Bakery products, for example, include the flour and all other ingredients used in their manufacture. Flour and flour mixes used in home baking are in grain mill products.

In 1869, 33 percent of all U.S. food never entered the marketing system. That food was produced and consumed by the same household, 10 percent by nonfarm households and 23 percent by farm families (fig. 3). Nonfarm home production includes game fish and animals for both nonfarm and farm families.

Home production has generally declined and now accounts for only 2 percent of food expenditures. Most home production now comes from nonfarm family gardens.

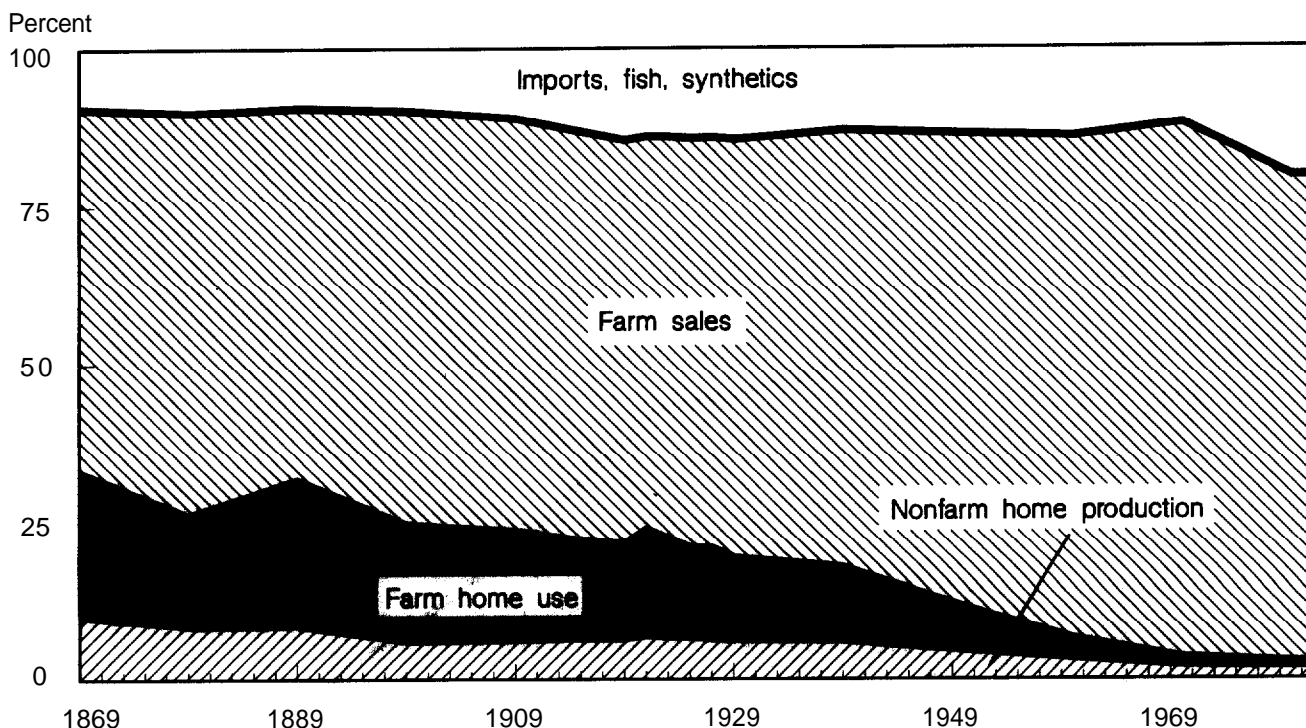

Most of the rest of the food comes from farm sales, but other products--imported foods, fish, and a few other nonfarm foods--accounted for 9-10 percent, mostly imported sugar, of the total in the 19th century. Imports and fish accounted for 12-14 percent of the total during 1914-70, sharply increasing by 1980 primarily because of much higher prices for fish and imported foods such as sugar and cocoa.

For a few individual products, chiefly milk, eggs, pork, and poultry, which were once widely produced for home consumption both by farm and nonfarm families, trends in consumption levels differ markedly when one separates home production from the commercial market.

The widest differences in consumption trends are found for fluid milk products (fig. 4). In 1910, about 37 percent of the population was consuming milk from the family cow or cows. Consumption levels in these households were more than twice as high as in households that purchased milk. Nearly 25 percent of home production was in nonfarm households. The proportion of households with a cow declined to about 28 percent in 1920, 20 percent in 1930 and 1940, 11 percent

Figure 3

Figure 4

Per capita consumption of fluid milk, by source of supply

Pounds

Share of households with own cow(s)

Percent

in 1950, and less than 1 percent in 1980. Since 1960, per capita milk consumption of all households has been about the same as that of households purchasing milk.

Home production and consumption of eggs are different. Although about 43 percent of all households raised chickens in 1910, calculated consumption levels were higher among those buying eggs than among those with their own flocks (fig. 5). Differences narrowed by 1930, and per capita consumption levels have been similar since then.

More than 60 percent of farm households and a few nonfarm households raised hogs in 1910. Households that raised hogs consumed about 50 percent more pork than did households that purchased pork (fig. 6). The proportion of farm families raising hogs stayed at about 50 percent through 1960, but has dropped since then.

Manufactured and Fresh Foods

The relative proportions of manufactured and fresh foods in the American diet have not changed as much as one might expect in more than a century. Fresh food accounted for 27 percent of food expenditures in 1869 and manufactured food for the remaining 73 percent. But not all manufactured foods came from factories. Manufactured products such as dressed meat, butter, and cheese produced on the farm or by retail butchers accounted for 49 percent of total food expenditures in 1869 (fig. 7). Only 15 percent was consumed on the same farm where produced. About 70 percent of the fresh products (fresh fruit and vegetables, eggs, fresh fish, game, and home-produced milk) were consumed where produced.

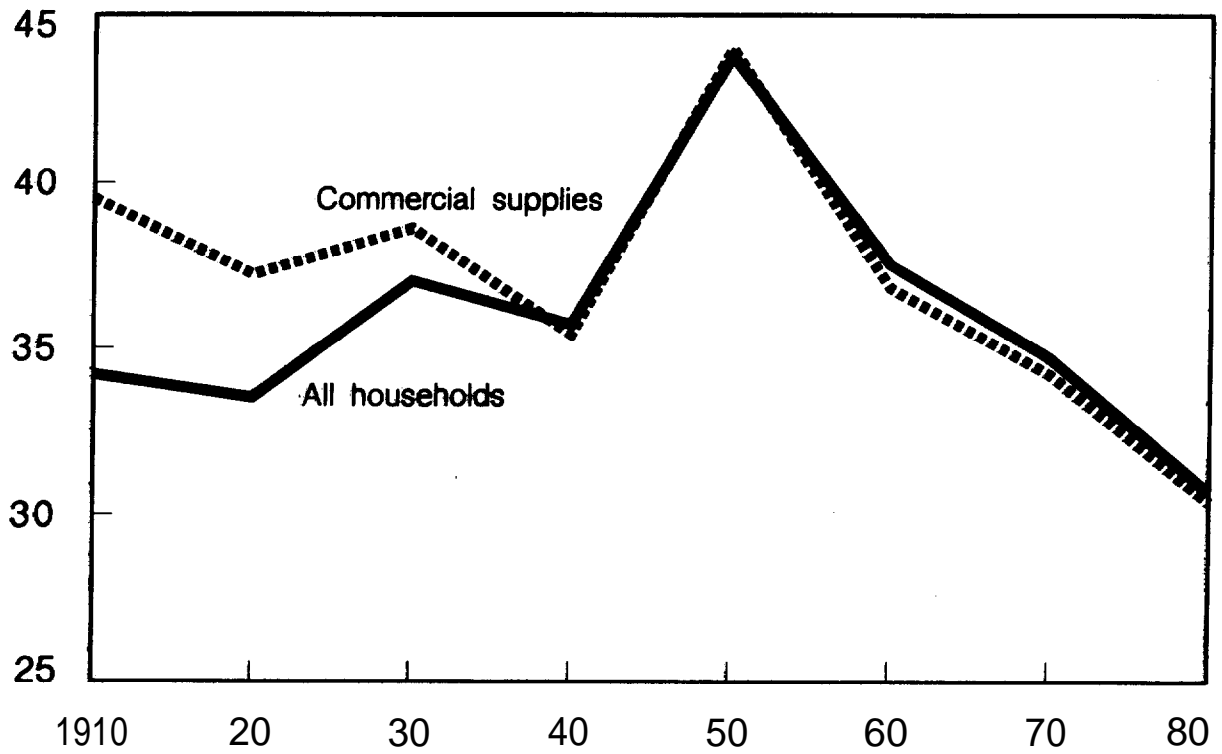

Commercial sales of fresh products increased substantially, from 8.5 percent in 1869 to 15.6 percent in 1909, mostly because of rapid growth in specialized truck farming and fruit growing. The development and introduction of refrigerated railroad cars made possible the movement of fresh fruits and vegetables thousands of miles.

Sales of fresh products held at 13-14 percent of total food expenditures into the 1950's and gradually declined to 10 percent in 1980. The share of manufactured food products coming from farm and retail sources is now insignificant. About all that is left on the farm is some fluid milk sold by producer-dealers and a little meat, most of which is custom slaughtered by locker plants. At retail, instore bakeries in supermarkets and fancy ice cream parlors show growing sales, and retail bake shops are regaining popularity.

The composition of consumer food products produced by manufacturers has changed dramatically over the years. In 1869, most fresh (chilled) meat was slaughtered and sold by retail butchers. Dressed poultry was not even enumerated in the Census of Manufactures until after 1909. The only factory dairy products were butter and cheese, although most of those products were still produced on the farm. Factory production of butter did not surpass that on farms until 1917. The important manufactured products were flour, corn meal, and other grain mill products which accounted for more than half of the total. The next most important product was sugar (table 14).

Flour and other grain products peaked at nearly 17 percent of total food supply in 1919, including substantial quantities produced for export to

war-torn Europe. Since World War II, flour and related products have accounted for about 3 percent of manufacturers' shipments. The value of baked goods, including cookies and crackers, is now much greater than that of consumer flour-related products. The shift in baking from home to factory is clearly reflected in these figures. In the 1970's, the most important product group was fresh meat and poultry; fruits, vegetables, and specialty foods were also large.

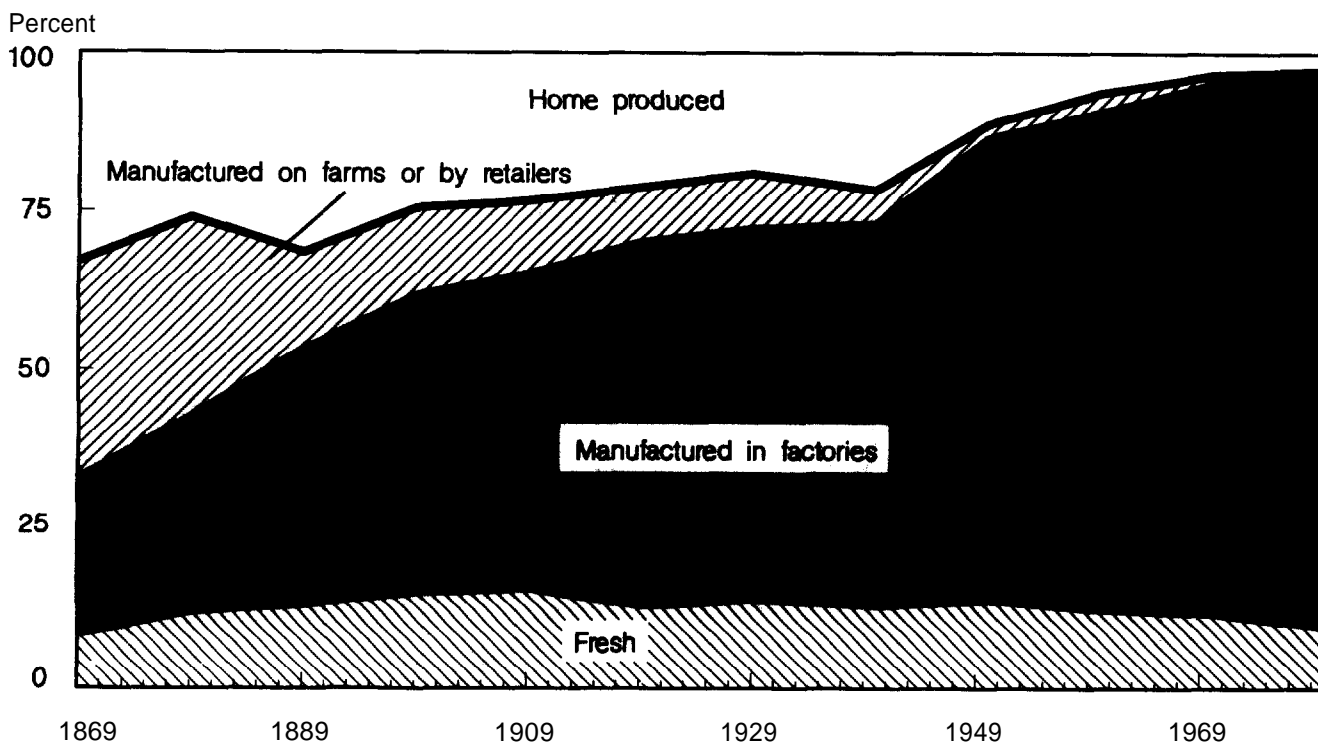

Consumer foods are far from the only products of the food and kindred products industry, as it is defined for census purposes (table 15). Other final products include alcoholic beverages, pet foods, prepared animal feeds, and ice. These products accounted for nearly \$38 billion in 1982. Intermediate products used in the manufacture of food have been at least 25 percent of final food products since 1939.

Who Pays for Food?

In 1985, families and individuals paid \$346 billion out of their own pockets for food consumed at home and away from home, plus a relatively small part of the 8 billion dollars' worth of home-produced food (such as for seed, fuel, and feed). Local, State, and Federal governments paid \$24 billion for food and businesses paid an additional \$34 billion.

Figure 7

U.S. food supply: Manufactured vs. fresh food

Source: App. table 11.

In 1985, the Federal share included \$18 billion for food stamps and donated foods, the cost of feeding the armed forces and prisoners in Federal institutions. Businesses pay for meals that they supply to their employees in restaurants and in institutions, business lunches, and meals on business trips. Federal, State, and local governments share part of the cost of the school food programs.

Leaving aside home-produced food, the share of all food at home and away from home paid for by families and individuals has gone down over the last half century, while the shares of both governments and businesses have increased (app. table 13).

Most of the data for the foregoing calculations are readily available as components of the food expenditure series. The one missing item is business expenditures for meals, either when traveling or entertaining clients. The figures used here are based on the expenditures for meals and snacks by families and individuals, as reported in the consumer expenditure surveys of 1950-51, 1960-61, and 1972-74 (USDL, BLS). Figures from the most recent Consumer Expenditures Survey, which is a continuing survey starting in 1980, have not yet been incorporated. In some years, those represented only the U.S. urban population.

Income and Expenditures

The share of income going for food is an indicator of affluence, either of a family or a nation. The figure has sometimes been misused to prove that food is a bargain, on which topic it provides no evidence at all.

Several problems, with no obvious answers, arise in making such a comparison. Each of these can be handled in more than one way, and alternative measures are given here.

Food produced at home is a small part of the total in recent years, but it was a major component of the food supply for most of our history. There is no completely satisfactory way of handling home-produced food in a comparison with income. It can be valued at the prices at which it could be purchased, as it is in this basic food expenditure series, or at the prices at which it could be sold. In either case, the value must be included in both expenditures and income. Because home-produced food is a larger proportion of food expenditures than of income, valuing home-produced food at retail rather than farm prices will increase the share of income spent for food over the years. If a measure of the out-of-pocket cost of home-produced food were available, a third comparison would be possible.

Valuing home-produced food at retail prices raises the calculated percentages of income spent for food by families and individuals, compared with valuing at farm prices (compare columns 2 and 3 in table 16). The difference was 2.4 percentage points in 1929, 2.3 in 1939, 0.7 in 1959, and 0.2-0.3 in the 1970's and 1980's. The difference was much larger in the 19th century when home-produced food was much more important. Valuing home-produced food at farm prices instead of retail prices in 1869 reduces the percentage of income spent for food from 60.6 percent to 50.9 percent.

The third problem area is food stamps. Until 1979, the Government's contribution of bonus stamps was tied to a purchase requirement. A recipient

family had to commit a portion of its own resources to the purchase of food in order to receive the Government contribution. Perhaps 60-70 percent of the Government's contribution resulted in increased food expenditures. With the removal of the purchase requirement, food stamps are effective in increasing food expenditures only for the poorest of the poor. Those persons above the minimum poverty level effectively receive an income supplement, and the effect on their food purchases is no different from that of a cash payment. These computations both include and exclude food stamps, with a similar amount included or excluded from income.

Adding food stamps both as an expenditure and income lowers the percentage of income spent for food (compare columns 3 and 4 of table 16). The experimental program lowered the share by 0.1 percentage point in 1940 and 1943. The pilot program of the 1960's had little effect, but the national program of the 1970's and 1980's lowered the share by 0.3-0.4 percentage point.

By all measures, the percentage of income spent for food has generally declined over the years. Since 1948, that share has declined in all but 3 years. Food expenditures by families and individuals ranged from 12.3-12.9 percent of income after taxes in 1985, depending on the treatment of these three areas.

-- = Not available.

Note: See app. table 14 for annual data since 1939. Income is disposable personal income (after taxes) adjusted for the method of valuing home-produced food and for food stamps, as appropriate.

1/ With home-produced foods at retail prices.

The only comparison before 1929 is for total food expenditures. It is not a "correct" comparison because it compares food expenditures from all sources, including governments and businesses, with the income of families and individuals. However, governments and businesses were less important participants before the Great Depression, so the comparison is not too bad (compare columns 1 and 3 of table 16). The difference was 1.7 percentage points in 1929.

Who Gets What?

Total expenditures for all purchased foods (excluding food produced at home) were \$338 billion in 1982. Out of this total, \$94 billion went to U.S. farmers, U.S. fishermen, and importers (table 17). A total of \$244 billion went to food processors, wholesalers, retailers, and food service operators. These figures include expenditures for food by both civilian and military installations, regardless of who paid for it, and include food produced on U.S. farms, fish, and imports. The food groups shown in table 17 relate to the origin of the products; in other words, all of the uses of meat products are compared with the farm or import value of meat. These calculations make extensive use of data such as that in table 5 (updated to 1982) on the value at retail store prices.

Meat in all products brought \$78 billion, 23 percent of the expenditures for all purchased food. The other groups had the following shares:

	<u>Percent</u>
Poultry and eggs	7
Seafood	2
Dairy	13
Fruits and vegetables	19
Grains	9
Other products	27

From 1960 to 1984, the farm value or equivalent of all food sold for domestic consumption increased 321 percent, the marketing bill 527 percent, and expenditures 444 percent (table 18). Much of the increase in the marketing bill is attributable to the great increase in eating out with the higher margins of food service establishments.

Outlets

Because the food expenditure series is built up from the sales of each type of store or other outlet, changes in the shares of different types of outlets are easily determined. But grocery stores include supermarkets, convenience stores, and other intermediate types of grocery stores. Breaking down the sales of grocery stores into these components requires some additional information. Convenience stores are defined by industry practice, and estimates of their sales are available from Progressive Grocer magazine. These data are used here. Supermarkets have been defined by industry practice in terms of minimum level of annual sales. Originally \$250,000 in the 1930's, the level has most recently been raised to \$2 million. Adjustments have been

made at discrete intervals, with resulting discontinuities in the definition of a supermarket. I have used an alternative approach. A supermarket is defined as a grocery store with annual sales of \$1 million or more in 1972. An index of the prices of all items sold in grocery stores was constructed, and minimum sales in all other years defined in then-current dollars. Thus, the minimum size in sales of a supermarket in 1982 was \$2.3 million, while in 1939 it was \$287,500 (table 19).

Although in 1929 there were a few grocery stores with sales of more than \$401,000, probably none of them had the other features of a supermarket, especially a self-service meat department. Supermarkets were basically a Great Depression development, with the emphasis on low operating costs and low prices. After World War II, the supermarket boom really took off. In 1982, 61 percent of all food sales for home use were through supermarkets (table 20).

Convenience stores were developed in the late 1950's, starting in the South and West. Many started as dairy stores, with milk products accounting for as much as 40-50 percent of their sales. Dairy products still play an important part in convenience store sales, but few of these stores have their sales concentrated as much as was once the case. In the last decade, the fastest growing items in convenience stores have been gasoline and carryout foods, including hot sandwiches.

Specialty food stores such as meat markets, bakeries, fruit and vegetable stores, and candy stores lost ground to the growing supermarkets for many years. Their share has declined irregularly.

In 1929, most of the "other stores" were general stores, the majority of which are gone now.

Home delivery, mostly of milk but also of bread and some grocery products, has been declining since 1939. The mail order share is small.

The most striking development in the away-from-home food market is the growth of fast food places (table 21). Their share has grown from 5 percent in 1958 to 30 percent in 1982. More traditional restaurants, lunchrooms, cafeterias, and caterers still have 40 percent of the market. Hotels and motels have had about 5-6 percent of the market since the mid-1950's, down from 10-11 percent in the 1930's. Schools and colleges peaked at 14 percent in 1967 with the baby boom of the post-World War II years and were about 10 percent of the total in 1982.

The foodservice market has been growing more rapidly than the offpremise food market since the Great Depression. Food service now accounts for 43 percent of all food dollars, compared with 19 percent in 1939 (fig. 8). Because the margins in food service are substantially higher than those in the offpremise market, the share of food at the same price level is somewhat less, 30 percent in 1984 and 17 percent in 1939.

The most important factor leading to the rising share of food service in food sales has been consumer income, which increased in nominal and real terms most of the time since the Great Depression (Lamm, 1982, p. 20). The sharp increase in the proportion of women working outside the home has contributed to both the rise in income and the demand for eating out.

Table 17--Farm value or equivalent, marketing bill, and expenditures
for all foods sold for domestic consumption, by farm product group, 1982

1963	762.9	21,167	31,484	8.6	59.9
1967	825.7	23,808	43,433	10.9	66.7
1972	1,000.0	27,231	64,960	14.0	69.6
1977	1,545.3	30,831	113,111	17.2	75.0
1982	2,313.2	26,640	175,655	14.4	74.5

1/ 1972 = \$1 million; other years calculated using an index of prices of all products sold in grocery stores. Sales include sales taxes.

In recent years, the competitive battle among food outlets has increasingly become one of supermarkets versus fast food outlets. During the postwar supermarket boom, real food sales in supermarkets grew at a rate of 13-15 percent per year until the mid-1950's. Sales of nonfoods grew even faster. During the 1960's, the rate of increase slowed to 4-5 percent as overstoreing (a saturation of available supermarket sites and of the market for their wares) became a problem. The 1970's brought a further slowing of the rate to less than 1 percent per year in sales of both food and nonfood. Even these modest increases are due largely to the addition of more services such as salad bars, instore bakeries, delicatessens, and eating facilities.

The fast-food boom came later, with sharp increases in the 1960's and early 1970's. That boom too has slowed as available sites filled and strings of fast-food places lined the highways and city streets. Fast-food outlets have emulated the supermarkets and sought to continue growth by tapping other markets. An increasing share of their sales is for offpremise consumption, reaching 34 percent of 1982 sales.

Thus, supermarkets and fast food outlets are edging into each other's territory. Convenience stores are also becoming more like fast-food outlets.'

The amount of money spent in food service establishments is a smaller share of the food expenditures of individuals and families than it is of total food expenditures. Governments account for much of the expenditures on food service in institutions, and businesses account for much of the expenditures in eating and drinking places. The share of personal food expenditures for food consumed away from home increased from 14.5 percent in 1929 to 20 percent in 1960, to 30 percent in 1975, and to 38 percent in 1985 (fig. 9).

Marketing Services

The marketing process for food consists of the addition of services to the basic commodities produced by farmers and fishermen here and abroad, including assembly, processing, transportation, and distribution. The output of marketing services can only be measured by indirect means, in contrast with the physical output of farming. A measure, in constant 1980 dollars, is obtained by valuing the marketing bill for all domestic food, the difference between the farm value (or equivalent for fish and imported foods) and expenditures, at 1980 prices.

In 1960, marketing services per person were 87.6 percent of the 1980 level and increased to 97.5 percent in 1972, dipped in 1973-75, and have changed little since then (fig. 9 and table 22). Most of the increase was in marketing services for food away from home. The real price of marketing services increased 37.7 percent between 1960 and 1982.

Labor productivity (output of food marketing services per hour of labor) increased sharply in the early 1960's, somewhat more modestly in the middle and late 1960's and early 1970's, peaking in 1972 at 108.9 percent of the 1980 level (fig. 10 and table 22). Productivity then declined until 1980, but recovered somewhat in 1981-82.

Because food service is more labor-intensive than other facets of food marketing, one would anticipate that the increasing share of away-from-home eating would hinder the growth of overall labor productivity in food

Figure 8

Food service as a share of all food

Source: App. table 17.

marketing. The increasing share of the relatively less labor-intensive fast food places might partially offset this tendency, as happened in the 1960's and 1980's, but not so much during 1972-80. Labor productivity in food marketing, excluding food service, increased 25 percent between 1960 and 1971, where it peaked 1.9 percent above the 1980 level. By 1982, productivity had risen 2.7 percent above the 1980 level.

Since 1937, the quantity of food marketing services per person has more than doubled (figs. 9 and 11). The data in these charts are not altogether comparable because of differences both in coverage (farm food versus all food) and in methodology. (See Waldorf, 1966, for the methods used in fig. 11; see also Ladd, 1961 and 1967, Lin and Seaver, 1976, and Waldorf, 1967.)

Between 1929 and 1962, the "real" price of marketing services for farm food (excluding food consumed away from home) declined a bit. "Real" prices fluctuated in the 1960's and then rose fairly sharply in the 1970's.

Waldorf (1966) analyzed the 1929-62 data to estimate price and income elasticities of demand for marketing services for farm food. He used both

ordinary least squares (OLS) and two stage least squares (TSLS). The independent (explanatory) variables included the real price of marketing services for farm food (deflated by the implicit price deflator for gross national product), per capita disposable income in constant dollars, and a time trend. His preferred equation omitted the trend variable and yielded an estimated income elasticity of +0.76. In other words, a 10-percent increase in per capita income was accompanied by a 7.6-percent increase in marketing services. He commented that the income variable should be looked upon as a gross demand shifter.

With the data on marketing services for all food for 1960-82 and the price measures presented in this report, a comparable analysis was performed. The results of that analysis are shown in table 23. The trend over time was significant in only one equation, and it had a negative effect at farm and retail levels and a small positive effect for marketing services. The small coefficients and lack of significance suggest that the trend can probably be omitted, as it was by Waldorf.

The price elasticity for marketing services is -0.06 and the income elasticity 0.30, although only income is significant at either the 5-percent or 10-percent level (equation 1). The associated demands at the farm and retail levels (equations 2 and 3) have the expected signs, and both price and income are significant.

Table 22--Food marketing services for sales for domestic use

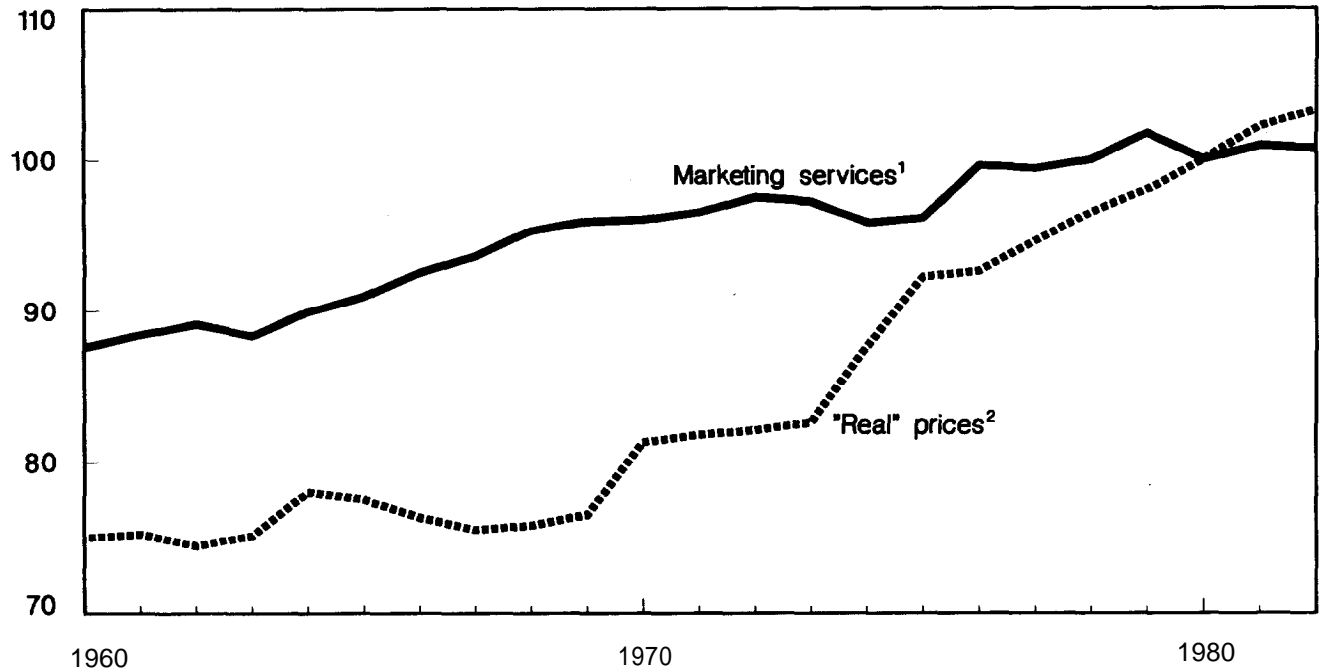

Year	Quantity of food marketing services per person 1/		Price of food marketing services		Labor productivity	
	Total	Excluding food service	Nominal 2 /	Real 2 /	Total	Excluding food service

Source: Adapted from Waldorf (1966), p. 43.

This analysis assumes that the demand for specific marketing services can be differentiated from the demand for the product with which those services are associated. Every product is associated with some services; one cannot buy a food product with no services. Some services are always included; for example, livestock must be slaughtered for meat, although the consumer could purchase the live animal and slaughter it. However, consumers may choose from a wide range of services. They can buy fresh, canned, or frozen vegetables in a wide variety of package sizes, and can buy many with added flavors and ingredients. One can purchase ready-to-bake biscuits, biscuit mix, or the separate ingredients. Away-from-home food service certainly is also available in many configurations. Examples could be multiplied almost without limit. Thus, the joint nature of the offering of a commodity and service does not prevent the consumer from exercising choice over a wide range of marketing services.

Table 23--Estimates of U.S. domestic demand for food marketing services and food products at farm and retail levels, 1960-82

Equation number	Dependent variable	Constant term	Coefficient and standard error (in parentheses) of--					R ²

1/ Marketing bill at 1980 prices, divided by resident population.
2/ Excludes marketing services in food service.
3/ Implicit price deflator for food marketing services.
4/ Nominal divided by implicit deflator for personal consumption expenditures less food and alcoholic beverages.
5/ Calculated from National Income and Product Accounts.
6/ Hired and unpaid labor in food manufacturing, transportation, warehousing, wholesaling, retailing, and food service. Includes only food for sale for domestic use (excludes labor on exports and nonfoods). Labor requirements in other (nonfood) stores calculated at the same rate as in grocery stores. Labor requirements in food service other than eating and drinking places calculated at the same rate per dollar of sales as in eating and drinking places.
7/ Excludes labor in food service.

1/ Pet food, feed, and ice subtracted.

METHODOLOGY

The method used to estimate most food expenditures starts with current estimates of sales or receipts. In 1980, this type of estimate accounted for 94 percent of food for offpremise use, 78 percent of meals and snacks, and 95 percent or more of all alcoholic beverages (app. tables 19 and 20).

Small amounts of data are based directly on reports of food expenditures--sales in railroad dining cars (NRPC, Amtrak) and airline payments for food service (CAB, 1979) (app. table 19, line 2).

Rough estimates of various types are used where no other method appears to be available. These estimates, accounting for less than 1 percent of each category, include lunchrooms in office buildings not operated by contractors, concessionaires, or independent operators (app. table 19, line 3).

For some categories, most notably hospitals and institutions, no data on food purchases were available either on a current or on a periodic basis (app. table 19, line 4). In these cases, base year data were supplied by one-time surveys, mostly for 1969 and 1979 from Van Dress (1971 and 1982). The estimates for other years were derived by using other series. For example, hospital and institutional use was estimated for other years using the base-year expenditures and an index incorporating number of residents and the whole-sale price index for food. Direct sales by farmers to consumers are based on a 1977 survey (USDA, ESCS, 1979).

Food furnished to civilian employees is taken directly from personal consumption expenditures of BEA (app. table 19, line 5) reported by the U.S. Department of Commerce (USDC, BEA).

Appendix table 19--Methods of estimating food expenditures, 1980

Method 1/	Food for offpremise use	Meals and snacks	: Packaged : alcoholic : beverages	Alcoholic drinks
	<u>Percent</u>			
Current sales or receipts	93.9	73.1	99.0	94.7
Reported	--	1.4	0	0
Rough estimates	.3	.5	.6	.9
Base year/mover	5.8	12.0	.4	4.4
Personal consumption expenditures component	0	2/ 3.7	0	0
Elementary and secondary schools	0	9.3	0	0

-- = Less than 0.05 percent.

1/ See text for description of each method.

2/ Meals served free to employees.

The estimates for elementary and secondary schools are based on data from Census reports, the National School Lunch Program, the School Breakfast Program, and the Special Milk Program (app. table 19, line 6). Sales (children's payments) are reported by the Census of Governments and annual Bureau of the Census reports of school finances since 1977. Before 1977, estimates were based on the data from USDA child nutrition programs (USDA, FNS) adjusted to totals for all school food service, including schools not participating in the Federal programs and a la carte service in participating schools. Estimates of total school food service were obtained from periodic national surveys (Anderson, 1958a, 1958b; Anderson and Hoofnagle, 1960; Freund, 1971; Kriesberg, 1964a, 1964b, 1965; Robinson, 1978; VanDress and Putnam, 1983).

Economic Research Service Data Bases Available

The U.S. Department of Agriculture's Economic Research Service has developed a series of computerized databases covering important elements of today's agribusiness and related activities here and abroad.

The data bases are:

Africa/Middle East Grain
Agricultural Outlook Yearbook
Cameroon's Grain
Egypt's Grain
Exchange Rates
Farm Income
Farm Machinery Statistics
Farm Real Estate
Fertilizer Use
Food, Beverages, and Tobacco
Irrigated Farms
Israel's Grain
Local Government Finances
Nigeria's Grain
Pesticide Use
Policy Impact Codes
Poultry and Egg Statistics
Rural Fire Protection Facilities
Saudi Arabia's Grain
Turkey's Grain
U.S. Dry Beans
World Production Indexes
